Abstract

We implement DCGAN on MNIST and SVHN dataset. The generated samples for both datasets are great although it takes quite some time to train the model. To help the model converge faster, we implement WGAN as well. The result **TBD**.

1 Introduction

Generative Adversarial Nets (GAN), first introduced by Ian Goodfellow in 2014[1], is a model that can be used to generate new images. It has been a hot topic since then.

The core idea of GAN is to create a two-player game. Build a generator that creates fake images while the discriminator tells whether the image is true or fake.

We train D to maximize the probability of assigning the correct label to both training examples and samples from G. We simultaneously train G to minimize $log(1 - D(G(z)))$.

The optimum case is that the generate can fully recover the distribution of the data and the discriminator cannot tell whether the image is fake or not i.e. the output of discriminator is $1/2$.

2 Implmentation on MNIST

2.1 Architecture

We used Deep Convoltional GAN (DCGAN)[2] as our structure.

2.1.1 Generator

- First layer: Dense
  - Input: 100×1 vector
  - Output $7 \times 7 \times 256$
  - Batch normalization
  - Activation: leaky relu
- Second layer: Conv2DTranspose
  - Filter: 128
  - Kernel size: 5
  - Stride: 1
  - Padding: same
  - Batch normalization
  - Activation: leaky relu

33rd Conference on Neural Information Processing Systems (NeurIPS 2019), Vancouver, Canada.

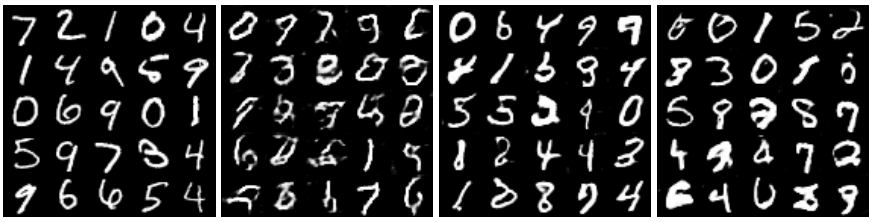
- Third layer: Conv2DTranspose
  - Filter: 64
  - Kernel size: 5
  - Stride: 2
  - Padding: same
  - Batch normalization
  - Activation: leaky relu
- Fourth layer: Conv2DTranspose
  - Filter: 1
  - Kernel size: 5
  - Stride: 2
  - Padding: same
  - Activation: tanh

2.1.2 Discriminator

- First layer: Conv2D
  - Input: $28 \times 28 \times 1$ array
  - Filter: 64
  - Kernel size: 5
  - Stride: 2
  - Padding: same
  - Activation: leaky relu
  - Dropout: 0.3
- Third layer: Conv2D
  - Filter: 128
  - Kernel size: 5
  - Stride: 2
  - Padding: same
  - Activation: leaky relu
  - Dropout: 0.3
- Fourth layer: Conv2D
  - Filter: 256
  - Kernel size: 5
  - Stride: 2
  - Padding: same
  - Activation: leaky relu
  - Dropout: 0.3
- Fifth layer: Flatten
- Sixth layer: Dense with output 1

2.1.3 Hyperparameters

- Epoch:
- Batch:
- Learning rate
  - Generator: 1e-3
  - Discriminator: 1e-4



(a) MNIST data (b) Epoch 10/50 (c) Epoch 30/50 (d) Epoch 50/50

Figure 1: Comparison of MNIST data and generated samples from DCGAN

2.2 Result

Training process in tensorboard

the generated samples compared with training dataset and figure 2a in paper

From Figure 1, we can see the generated samples has a good approximation after 30 epoches.

The samples from 10th are quite blury and they cannot have a good representation of number 2, 5, 8, etc.

The latter samples are clearer and the edges of the numbers are smoother. Number 0, 1, 3, 5, 7, 9 are quite ideal.

3 Implmentation on SVHN

3.1 Architecture

3.1.1 Generator

The generator is slightly modifed from the generator for MNIST. The output of the first dense layer is changed to $8 \times 8 \times 256$ and the filter of the fourth layer (Conv2DTranspose) has changed from 1 to 3 so that the output of the whole generator would be a $32 \times 32 \times 3$ image.

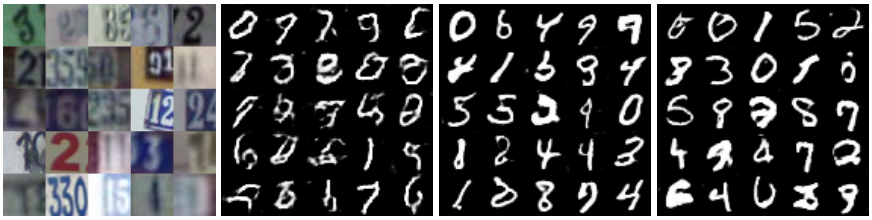
3.1.2 Discriminator

Discriminator is exactly the same as the previous one.

3.2 Result

Training process in tensorboard

the generated samples compared with training dataset



(a) SVHN data (b) Epoch 10/50 (c) Epoch 30/50 (d) Epoch 50/50

Figure 2: Comparison of MNIST data and generated samples from DCGAN

How is the quality compared to your GAN on MNIST? If the training does not go well, what failure modes do you see?

4 WGAN

Wasserstein GAN is a modified GAN introduced by Arjovsky, Martin, et al.(2017)[3]. It proposed Wasserstein that has a better property than Jensen-Shannon divergence.
